**(54) Title:** LIQUID MANAGEMENT FILM FOR ABSORBENT ARTICLES

**(57) Abstract**

There is provided a liquid management film for use in rapid transport of liquid. The liquid management film is a thermoplastic film having at least one microstructured hydrophilic surface with a plurality of primary grooves. The primary grooves have at least two secondary grooves, each of said secondary grooves forming at least one notch which notches are substantially parallel and separated by a secondary peak. The notches or secondary grooves have an included angle of from about 10° to about 120°, the depth of one of said secondary grooves (the height of the secondary peak over the notch) being at least 5 microns and said depth being from about 0.5 to about 80 percent of the depth of the primary groove. The said notches have a radius of curvature of less than about 15 microns and the primary and/or secondary groove depth and width varies by less than 20 percent for each groove over a given length of the film.

5           **LIQUID MANAGEMENT FILM FOR ABSORBENT ARTICLES**Background of the Invention

10       The present invention relates to liquid management films for liquid transport for use in articles such as absorbent articles such as meat tray liners, bed pads, baby diapers, sanitary napkins, and adult incontinent pads.

15       Disposable absorbent articles typically comprise three basic components: a liquid permeable topsheet that is located closest to the skin of the wearer when the article is in use, an absorbent core, and a liquid impermeable barrier sheet which is located on the opposite side of the absorbent core. Other components  
20       such as fastening tapes, leg and waist elastics, etc. are also commonly used.

      The absorbent core receives and retains liquids that pass through the liquid permeable topsheet and typically comprises a batt of wood fluff fibers.  
25       Superabsorbent materials, typically in powder form, are often distributed within the absorbent core to enhance its liquid holding capacity and liquid retention properties.

      One problem associated with absorbent articles is  
30       the inefficient utilization of the total absorptive capacity of the absorbent core material. This is due in part because absorbent articles normally have an elongated rectangular or hourglass shape and the liquid introduction or insult and spreading of liquid is often  
35       confined to the central area of the absorbent core.

      Another problem associated with absorbent articles is the inability of the absorbent core to absorb liquids rapidly enough when large amounts of liquid are discharged into the absorbent core over short periods  
40       of time. This often results in undesirable side leakage.

5           To improve the liquid acquisition and lateral  
spreading properties of absorbent articles, many  
products have utilized a wicking layer of tissue or  
crepe or a nonwoven. This wicking layer can be located  
between the liquid permeable topsheet and the absorbent  
10   core, in the center of the absorbent core, or in the  
absorbent core in a location closer to the liquid  
impermeable barrier sheet. However, tissue, crepe or  
nonwovens tend to promote isotropic spreading of  
liquids. That is, liquid tends to spread at similar  
15   rates in both the lengthwise and width directions of  
the absorbent article. As a result, in many instances  
where the core is elongate, the liquid will leak beyond  
the side edges of the absorbent article before it has  
an opportunity to spread to the ends of the absorbent  
20   core. U.S. Patent No. 4,643,727 proposes a wicking  
layer, such as paper toweling, wrapped around a plastic  
bubble layer. WO 86/02543 proposes a wicking layer of  
tissue covering a corrugated laminate coated with  
superabsorbent particles. In U.S. Patent No. 5,037,409  
25   (Chen) a flow modulating layer is proposed which is  
preferably formed of a hydrophilic melt-blown nonwoven  
microfiber web. Likewise, U.S. Patent No. 4,908,026  
proposes a "flow control layer" which is placed between  
the absorbent core and a perforated topsheet where the  
30   "flow control layer" is a melt-blown nonwoven,  
preferably treated to be hydrophilic.

Numerous other approaches have been suggested for  
improving the liquid distribution and absorption  
properties of absorbent articles. Many investigations  
35   have proposed the use of channels, reservoirs,  
apertures, etc., that have been introduced generally  
into the wood fluff absorbent core and occasionally  
into the tissue wicking layer by methods such as  
embossing, corrugation, cutting or folding. See, for  
40   example, U.S. Patent Nos. 4,676,786 (Nishino),  
4,678,464 (Holtman), 4,655,759 (Romans-Hess et al.),

5 5,030,229 (Yang), 3,769,978 (DeNight et al.), 4,758,240  
(Glassman), 4,795,453 (Wolfe), U.K. Patent No.  
2,017,505 (Fitzgerald) and WO 86/01378 (Kamstrup-  
Larson). In WO 91/11161 there is proposed corrugation  
of the nonwoven liquid permeable topsheet of an  
10 absorbent product.

U.S. Patent No. 4,735,624 (Mazars) discloses a  
disposable diaper comprising an absorbent pad  
constituted by an absorbent material consisting  
essentially of hydrophilic fibers joined to one another  
15 to form a coherent mass. The pad is narrow in the  
crotch area and widens out in the front and rear areas  
of the diaper with branches.

The use of a plastic netting material to promote  
the unidirectional spreading of liquids in absorbent  
20 pads, is disclosed in European Patent No. 0 174 152 B1.

The use of certain complex shaped fibers, in tow or  
staple form, that are capable of transporting liquid in  
absorbent articles are disclosed in European Patent  
Application (E.P.A.) No. 0 391 814 A2 (Phillips et al.)  
25 and WO 91/12949 (Thompson) (who discloses fibers or  
sheets with an extremely large ratio of surface area to  
mass), and E.P.A. No. 493 728 A1 which discloses a  
notched fiber with notch angles ( $\alpha$ ) less than  $(180^\circ -$   
 $2\theta)$ , where  $\theta$  is the liquid fiber contact angle.

30 U.S. Patent No. 4,798,604 (Carter) discloses a  
contoured polymeric film which is apertured and  
contains a pattern of raised areas that may be employed  
to form the body contacting surface, i.e., topsheet, in  
absorbent devices. Films have also been proposed as  
35 liquid distribution layers in absorbent articles in WO  
95/00093 where a liquid distribution strip is used in  
association with an absorbent strip. The liquid  
distribution strip is shorter and wider than the  
absorbent strip. The two strips are located between  
40 the topsheet and the absorbent core of the absorbent  
article (e.g., a sanitary napkin). The liquid

5 distribution strip can be a polyethylene film which can be apertured and in one alternative embodiment has troughs. In French Patent No. 2,082,526 a diaper or tampon is provided with a drain that is a pleated sheet of nonwoven placed in the absorbent pad.

10 Despite these previously known technologies, additional improvements to obtain more efficient and speedier absorption by absorbent cores without leaking are desired.

15 Summary of Invention

The present invention provides liquid management films that facilitate desired rapid and uniform anisotropic or directionally dependent distribution of liquids, and absorbent articles using these films that exhibit excellent liquid acquisition and distribution, resulting in greater effective absorption capacity and greater comfort for the wearer.

In brief summary, articles using the invention liquid management film typically comprise a liquid permeable topsheet, a backsheet, sometimes preferably liquid impermeable, and an absorbent core disposed between the topsheet and backsheet, wherein the article further comprises at least one liquid management film that promotes rapid directional spreading of liquids.

25 The liquid management film is a sheet, typically flexible, having at least one microstructure-bearing hydrophilic surface with a plurality of primary grooves with nested secondary grooves therein. When an absorbent article is assembled, the hydrophilic surface is in contact with the absorbent core. In some

35 embodiments, the liquid management film is preferably impermeable, i.e., although its surface is hydrophilic the film does not transmit liquid through its body from one surface to the other surface in undesirable

40 fashion. In some embodiments, the liquid management film (which may be impermeable or not as desired) has

5 one or more apertures therein to permit controlled transmission of liquid therethrough in a desired manner.

The invention liquid management film has at least one microstructured hydrophilic surface with a  
10 plurality of primary grooves to promote the undirectional spreading of liquids, a plurality of said primary grooves, each primary groove having at least two secondary grooves. The secondary grooves each forming at least one notch which notches are  
15 substantially parallel and separated by a secondary peak which secondary grooves have an included angle of from about 10° to about 120°. The depth of one of the secondary grooves (the height of the secondary peak over the notch) is at least 5 µm and generally about  
20 0.5 to about 80 percent of the depth of the primary grooves. The notches have a radius of curvature of less than about 15 microns. Generally the primary or secondary grooves can be V-shaped or rectangular. Generally only the secondary grooves include notches.

25 Articles of the invention may be made in the form of meat tray liners, bed pads, diapers, adult incontinent devices, and feminine hygiene products.

#### Brief Description of Drawing

30 The invention will be further explained with reference to the drawing, wherein:

Figs. 1, 2 and 3 are cross-sectional cutaway views of illustrative embodiments of liquid management films of the invention;

35 Fig. 4 is a elevational view of one embodiment of a diaper of the invention;

Fig. 5 is a cross-sectional illustration of the diaper of Fig. 4;

40 Figs. 6 and 7 are elevational views of two other embodiments of diapers of the invention;

5 Figs. 8a and 8b are schematic diagrams used to illustrate interaction of a liquid on a surface;

Figs. 9 through 11 are cross-sectional illustrations of portions of films with channels having different cross-sectional profiles;

10 Fig. 12 is a cross-sectional illustration of another embodiment of a diaper of the invention; and

Fig. 13 is a cross-sectional illustration of another embodiment of an absorbent article of the invention.

15 Fig 14 is a cross-sectional view of another liquid management film of the invention.

These figures, which are idealized, are not to scale and are intended to be merely illustrative and non-limiting.

20

#### Detailed Description of Illustrative Embodiments

Liquid management films of the invention are in the form of sheets or films rather than a mass of fibers. The grooves of liquid management films of the invention provide more effective liquid flow than is achieved with webs or tows formed from fibers. The walls of channels or grooves formed in fibers will exhibit undulations and complex surfaces that interfere with flow of liquid through the channels or grooves.

25 In contrast, the grooves in the invention sheets or films are uniform and regular along substantially each groove length and preferably from groove to groove.

Liquid management films of the present invention are capable of spontaneously and uniformly transporting liquids along the axis of the film grooves. Two general factors that influence the ability of liquid management films to spontaneously transport liquids (e.g., water, urine or vaginal secretions) are 1) the geometry of the surface (capillarity, shape of the grooves) and 2) the nature of the film surface (e.g., surface energy).

30  
35  
40

5           The grooves of liquid management films of the  
present invention can be of any geometry that provides  
desired liquid transport, and preferably one which is  
readily replicated. With reference to Fig. 1, one  
preferred geometry is a rectilinear primary groove or  
10   channel 2 in a flat film 1. The primary groove 2 has  
included secondary grooves 3 which forms a multitude of  
notches 5. The notches 5 (or secondary grooves 3,  
where the grooves are V-shaped and have substantially  
straight sidewalls) have an included angle of (i.e.,  
15   angle Alpha) from about 10° to about 120°, preferably  
from about 10° to about 100°, and most preferably from  
about 20° to about 95°. The notch included angle is  
generally the secant angle taken from the notch to a  
point 2 to 1000 microns from the notch on the sidewalls  
20   forming the notch, preferably the included angle is the  
secant angle taken at a point halfway up the secondary  
groove sidewalls. It has been observed that notches  
with narrower included angular widths generally provide  
greater vertical wicking distance. However, if Alpha  
25   is too narrow, the wicking action will become  
significantly lower. If Alpha is too wide, the notch  
or secondary groove may fail to provide desired wicking  
action. As Alpha gets narrower, the contact angle of  
the liquid need not be as low, to get similar liquid  
30   transport, as the contact angle must be for notches or  
grooves with higher angular widths.

          The primary groove included angle is not critical  
except in that it should not be so wide that the  
primary groove is ineffective in channeling liquid.  
35   Generally, the primary groove maximum width is less  
than 3000 microns and preferably less than 1500  
microns. The included angle of a V-groove shaped  
primary groove will generally be from about 10 degrees  
to 120 degrees, preferably 30 to 90 degrees. If the  
40   included angle of the primary groove is too narrow, the  
primary groove may not have sufficient width at its

5 base so that it is capable of accommodating an adequate  
number of secondary grooves. Generally, it is  
preferred that the included angle of the primary groove  
be greater than the included angle of the secondary  
grooves so as to accommodate the two or more secondary  
10 grooves at the base of the primary groove. Generally,  
the secondary grooves have an included angle at least  
20 percent smaller than the included angle of the  
primary groove (for V-shaped primary grooves).

The depth of the primary grooves (2, 22) (the  
15 height of the peaks or tops above the lowermost groove  
notch), "d", is substantially uniform, and is typically  
from about 50 to about 3000 microns, preferably from  
about 75 to about 1500 microns, and most preferably is  
from about 100 to about 1000 microns. It will be  
20 understood that in some embodiments films with grooves  
(2, 22) having depths larger than the indicated ranges  
may be used. If the grooves are unduly deep, the  
overall thickness of the liquid management film will be  
unnecessarily high and the film may tend to be stiffer  
25 than is desired. The width of the primary groove at  
its base is sufficient to accommodate two or more  
secondary grooves.

When used in absorbent articles it is typically  
preferred that the liquid management films be thin and  
30 flexible to avoid imparting undesirable stiffness to  
the absorbent articles. For instance, in the case of  
liquid management films used in infant diapers or adult  
incontinent devices, the average film thickness from  
the front face to the back face of the film typically  
35 ranges from about 25 to about 1500 microns, preferably  
from about 125 to about 1000 microns. The liquid  
management film should be sufficiently thick to retain  
its structural integrity when subjected to stresses  
(e.g., stretching and flexing) expected to be  
40 encountered during use. A preferred liquid management  
film has a plurality of parallel thin film regions

5 (e.g., which can be down to about 10 microns thick)  
with thicker film regions forming the primary and  
secondary peaks. These thin film regions are formed  
with rectangular shaped secondary grooves where the  
secondary groove bottoms (generally at least 3 microns  
10 wide, preferably at least 5 microns wide) define the  
parallel thin regions. This provides a film with  
improved flexibility even when the average film  
thickness is on the higher end of the above range. In  
the case of bed pads, the absorbent article need not be  
15 as highly flexible to provide comfort and the liquid  
management film may be up to 3000 microns or more  
thick.

The invention liquid management films can be  
formed from any thermoplastic materials suitable for  
20 casting, or embossing including, for example,  
polyolefins, polyesters, polyamides, poly(vinyl  
chloride), etc. Polyolefins are preferred,  
particularly polyethylene or polypropylene, blends  
and/or copolymers thereof, and copolymers of propylene  
25 and/or ethylene with minor proportions of other  
monomers, such as ethylene/vinyl acetate. Polyolefins  
are preferred because of their excellent physical  
properties, ease of processing, and typically lower  
cost than other thermoplastic materials having similar  
30 characteristics. Polyolefins readily replicate the  
surface of a casting or embossing roll. They are  
tough, durable and hold their shape well, thus making  
such films easy to handle after the casting or  
embossing process. Alternatively, liquid management  
35 films can be cast from curable resin materials such as  
acrylates or epoxies, and cured by exposure to heat or  
UV or E-beam radiation. Preferably, the liquid  
management film substantially retains its geometry and  
surface characteristics upon exposure to liquids.

40 Generally, the susceptibility of a solid surface  
to be wet out by a liquid is characterized by the

5 contact angle that the liquid makes with the solid  
surface after being deposited on the horizontally  
disposed surface and allowed to stabilize thereon. It  
is sometimes referred to as the "static equilibrium  
contact angle", sometimes referred to herein merely as  
10 "contact angle". As shown in Figs. 8a and 8b, the  
contact angle  $\Theta$  is the angle between a line tangent  
to the surface of a bead of liquid on a surface at its  
point of contact to the surface and the plane of the  
surface. A bead of liquid whose tangent was  
15 perpendicular to the plane of the surface would have a  
contact angle of  $90^\circ$ . Typically, if the contact angle  
is  $90^\circ$  or less, as shown in Fig. 8a, the solid surface  
is considered to be wet by the liquid. Surfaces on  
which drops of water or aqueous solutions exhibit a  
20 contact angle of less than  $90^\circ$  are commonly referred to  
as "hydrophilic". As used herein, "hydrophilic" is  
used only to refer to the surface characteristics of a  
material, i.e., that it is wet by aqueous solutions,  
and does not express whether or not the material  
25 absorbs aqueous solutions. Accordingly, a material may  
be referred to as hydrophilic whether or not a sheet of  
the material is impermeable or permeable to aqueous  
solutions. Thus, hydrophilic films used in liquid  
management films of the invention may be formed from  
30 films prepared from resin materials that are inherently  
hydrophilic, such as for example, poly(vinyl alcohol).  
Liquids which yield a contact angle of near zero on a  
surface are considered to completely wet out the  
surface. Polyolefins, however, are typically  
35 inherently hydrophobic, and the contact angle of a  
polyolefin film, such as polyethylene or polypropylene,  
with water is typically greater than  $90^\circ$ , such as shown  
in Fig. 8b. Body liquids that will come into contact  
with the liquid management films of the present  
40 invention are aqueous. Thus, if such films are used as  
liquid management films of the invention, they must be

5 modified, e.g., by surface treatment, application of  
surface coatings, or incorporation of selected agents,  
such that the surface is rendered hydrophilic so as to  
exhibit a contact angle of  $90^\circ$  or less, thereby  
enhancing the wetting and liquid transport properties  
10 of the liquid management film.

In liquid management films of the invention, the  
desired surface energy of the microstructured surface  
of V-grooved liquid management films is such that:

$$15 \quad \Theta \leq (90^\circ - \alpha/2),$$

wherein  $\Theta$  is the contact angle of the liquid with  
the film and  $\alpha$  is the average included angle of  
the secondary V-groove notches.

20 Any suitable known method may be utilized to  
achieve a hydrophilic surface on liquid management  
films of the present invention. Surface treatments may  
be employed such as topical application of a  
surfactant, plasma treatment, grafting hydrophilic  
25 moieties onto the film surface, sol-gel coating, corona  
or flame treatment, etc. Alternatively, a surfactant  
or other suitable agent may be blended with the resin  
as an internal additive at the time of film extrusion.

It is typically preferred to incorporate a surfactant  
30 in the polymeric composition from which the liquid  
management film is made rather than rely upon topical  
application of a surfactant coating. Topically applied  
coatings tend to fill in, i.e., blunt, the notches of  
the channels, thereby interfering with the desired  
35 liquid flow to which the invention is directed. An  
illustrative example of a surfactant that can be  
incorporated in polyethylene liquid management films is  
TRITON™ X-100, an octylphenoxypolyethoxyethanol  
nonionic surfactant, e.g., used at between about 0.1  
40 and 0.5 weight percent. An illustrative method for  
surface modification of the films of the present

- 5 invention is the topical application of a 1 percent aqueous solution of the reaction product comprising 90 weight percent or more of:

wherein n=8 (97 percent), n=7 (3 percent), and 10 weight percent or less of:

wherein n=8 (97 percent), n=7 (3 percent). Preparation of such agents is disclosed in U.S. Patent No. 2,915,554 (Ahlbrecht et al.)

- 20 In some embodiments, the liquid management film 1 will have primary grooves or channels on only one major surface as shown in Fig. 1. In other embodiments, however, liquid management film (1, 12) will have primary grooves or channels on both major surfaces, as
- 25 shown in Figs. 2 and 3. Typically in the case of absorbent articles such as diapers, if the film has primary channels or grooves on both major surfaces, the primary channels or grooves on one surface are substantially parallel to those on the other surface.
- 30 The primary channels or grooves 22 may be laterally offset from one surface to the other surface as shown in Fig. 2 or may be aligned directly opposite each other as shown in Fig. 3. A liquid management film with offset grooves or channels as shown in Fig. 2
- 35 provides a maximum amount of surface area for wicking while at the same time using a minimum amount of material. In addition, a liquid management film with offset channels or grooves can be made so as to feel

5 softer, due to the reduced thickness and boardiness of  
the sheet, than a liquid management film with aligned  
channels as shown in Fig. 3. As shown in Fig. 3, liquid  
management films 12 of the invention may have one or  
more apertures 24 therein, which enable a portion of  
10 the liquid in contact with the front surface of the  
liquid management film to be transported to the back  
surface of the film, to improve liquid control. The  
apertures need not be aligned with the notch of a  
channel and do not need to be of about equal width as  
15 the channels. The surfaces of the liquid management  
film within the apertures is preferably hydrophilic.

In each primary groove 2 are at least two  
secondary grooves (3, 23) and at least two notches (5,  
25), the notch (5, 25) or notches of each secondary  
20 groove (3, 23) is separated by a secondary peak (6,  
26). Generally, each secondary groove will generally  
have only one notch, but a secondary groove will have  
two notches if the secondary groove is rectangular.  
The secondary peak (6, 26) for V-groove shaped  
25 secondary grooves is generally characterized by an  
included angle  $\beta$  which is generally equal to  $(\alpha^1 + \alpha^2)/2$   
where  $\alpha^1$  and  $\alpha^2$  are the included angles of the two  
adjacent V-groove shaped secondary grooves (3, 23),  
assuming that the two sidewalls forming each secondary  
30 groove are symmetrical and not curved. Generally, the  
angle  $\beta$  would be from about  $10^\circ$  to about  $120^\circ$ ,  
preferably from about  $10^\circ$  to about  $90^\circ$ , and most  
preferably from about  $20^\circ$  to about  $60^\circ$ . The secondary  
peak could also be flat (in which case the included  
35 angle would theoretically be  $0^\circ$ ) or even curved, e.g.,  
convex or concave, with no distinct top or included  
angle. Preferably, there are at least three secondary  
grooves (3, 23) and/or at least three notches for each  
primary groove (2, 22), included any notches (5, 25)  
40 associated with the end grooves (notches 8 or 9) as  
shown in Fig. 1.

5           The depth of one of the secondary grooves (3, 23)  
(the height of the top of the secondary peaks 6 over  
the notches 5) is uniform over the length of the liquid  
management films, and is typically at least 5 microns.

10           The depth of the secondary grooves (3, 23) is  
generally 0.5 to 80 percent of the depth of the primary  
grooves, preferably 5 to 50 percent. The spacing of  
the notches (5, 25) on either side of a peak 6 is also  
preferably uniform over the length of the liquid  
management film. Preferably the primary and/or  
15           secondary groove depth and width varies by less than 20  
percent, preferably less than 10 percent for each  
groove over a given length of the liquid management  
film. Variation in the secondary groove depth and  
shape above this range has a substantial adverse impact  
20           on the rate and uniformity of liquid transport along  
the liquid management film. Generally the primary and  
secondary grooves are continuous and undisturbed.

          Liquid management film (1, 12) can be incorporated  
into a disposable absorbent article 10 in a number of  
25           ways. The film can be cut into one or more generally  
longitudinal strips that can be placed above, below, or  
within the absorbent core in a variety of  
configurations. Several illustrative embodiments are  
depicted in Figs. 4, 6 and 7. Figs. 4 and 5 show one  
30           embodiment of a diaper 10 comprising the invention  
liquid management film 12. Diaper 10 also comprises  
liquid permeable topsheet 14, liquid impermeable  
backsheet 16, and absorbent core 18. Diaper 510 in  
Fig. 6 has three liquid management films 512 with  
35           channels 521 arranged in parallel strips in absorbent  
core 518. Diaper 610 in Fig. 7 has two liquid  
management films 612 overlaid in an intersecting or "X"  
pattern in absorbent core 618. Typically, the  
intersection will be located where liquid introduction  
40           is expected.

5           If desired, the liquid management films may be disposed on the interior surface of the backsheet or even made integral therewith by forming the desired microstructured surface on the interior surface thereof. In this embodiment, the microstructured film  
10 serves two functions, as a liquid transport layer adjacent to the underside of the absorbent core and as a liquid barrier layer for the absorbent article. Fig. 12 illustrates diaper 120 comprising liquid permeable topsheet 1214, liquid impermeable backsheet 1216, and  
15 absorbent core 1218. Liquid management film 1212, with microstructured surface 1220 with primary grooves 1222, is disposed on the interior surface of backsheet 1216.

          If desired, grooves 1222 may be formed on the surface of backsheet 1216 such that the liquid management film  
20 and backsheet are of unitary construction.

          A Preferred microstructure are ones in which the secondary grooves are V-shaped grooves or rectilinear shaped grooves, i.e., each groove is defined by at least a pair of planar walls which meet at at least one  
25 line of intersection which lines of intersection form a notch. Such channels are easily formed and provide rapid liquid transport. In other embodiments, the sides of the primary or secondary grooves need not be planar but each secondary groove preferably possesses  
30 at least one notch that extends parallel to the longitudinal axis of the groove. In other words, when viewed in cross-section, the line of intersection of a plane perpendicular to the axis of the groove and the walls of the groove preferably possesses an abrupt  
35 slope change, i.e., a geometric discontinuity or a point where the first order derivative of the surface of the groove has multiple values.

          Although preferred, the notch need not be a perfect point; typically, useful liquid management is  
40 achieved if the notch has a radius of curvature of about 15 microns or less, preferably about 10 microns

5 or less, and more preferably about 5 microns or less.  
It has been observed that coatings applied to  
microstructured surfaces to impart desired  
hydrophilicity thereto may tend to aggregate or pool in  
the base of the grooves, tending to increase the radius  
10 of curvature of the notch (3, 23).

Fig. 9 shows a typical film with V-shaped primary  
and secondary grooves 22 and having a multitude of  
notches or abrupt slope changes 25. Fig. 10 shows a  
film with primary grooves 921 having non-planar,  
15 inwardly flaring walls and a base with abrupt slope  
change or notches 925 in secondary grooves 923. The  
liquid management film in Fig. 10 has large crests or  
tops 924 between adjacent primary grooves 921. It is  
typically preferred to have narrow crests or, as shown  
20 in Fig. 9, closely packed primary grooves such that the  
walls of adjacent channels are in contact in order to  
increase the number of grooves per unit surface width.

Preferably the primary and secondary groove walls  
are smooth because an excessive amount of surface  
25 roughness will tend to impede desired liquid flow.  
Liquid management films with groove walls that flare  
outwardly as shown in Fig. 11 are believed to provide  
an optimum combination of rapid anisotropic liquid flow  
and vertical wicking capability and accordingly are  
30 preferred for many applications. Fig. 11 shows a  
liquid management film 1110 with primary grooves 1121  
with secondary grooves 1123 and notches 1125 and walls  
that flare outward rather than straight. For ease of  
manufacture the walls meet at secondary crests or peaks  
35 1126 with a minimum of land area.

The primary and secondary grooves in the liquid  
management films of the invention are preferably  
oriented in the same direction, i.e., they are  
substantially parallel throughout their entire length.  
40 Grooves are considered to be substantially parallel as  
long as they extend in the same general direction

5 without intersecting; their lateral spacing need not be equal over their entire length but the groove depth and shape is substantially uniform over the entire film length.

10 In a typical absorbent article of the invention as shown in Fig. 4, absorbent core 18 and liquid management film 12 are both elongate and oriented in the same general direction. It is typically preferred that the liquid management film be substantially coextensive with the absorbent core i.e., extend to 15 within about 1 to 2 centimeters of the edge of the absorbent core in most cases. It is also typically preferred that it not extend beyond the absorbent core as this may result in leaking. In such instances, the grooves of the liquid management film will typically be 20 oriented along the longitudinal axis of the film and of the absorbent core. Referring again to Fig. 4, it will typically be preferred in such instances for the lateral spacing of primary grooves 22 to vary along their longitudinal axis with the spacing being at a 25 minimum in a longitudinally interior region of film 12 and being wider than the minimum at an exterior region of film 12. Such an article is typically constructed such that the region of minimum lateral spacing is located near expected liquid insult with the wider 30 spacing being located at more distant locations. In such embodiments, liquid management film 12 provides both improved transport of the liquid away from the insult but also improved distribution of the liquid to more distant portions of absorbent core 18. If 35 desired, additional primary grooves (not shown) may begin between the interior region and longitudinal edges of liquid management film 12.

Fig. 13 shows another embodiment of the invention with absorbent article 1300 comprising liquid 40 management film 1302 with microstructure-bearing surface 1304, absorbent mass 1306, and attachment film

5 1308 on at least one side. Attachment film 1308 is  
selected in part based on the substrate to which the  
absorbent article is to be attached. Illustrative  
examples include suitable adhesives. Other  
illustrative examples include a component of a hook and  
10 loop fastening system, i.e., a strip of hook material  
with the strip of loop material being applied to a  
substrate.

Usually the microstructured surface is in contact  
with the absorbent core. However, in some embodiments,  
15 for instance where the absorbent material is subject to  
gel blocking, the liquid management film will be  
oriented such that a microstructure-bearing surface and  
the absorbent core are disposed on opposite sides of  
the liquid management film. In such embodiments, the  
20 liquid management film is preferably smaller than the  
absorbent core and/or has apertures therein. In some  
embodiments, the liquid management film may comprise  
another microstructure-bearing surface as described  
herein on the same side as the absorbent core.

25 In addition to absorbent articles with absorbent  
cores, the absorbent core could be an absorbent sheet  
or fabric such as might be found in a headband, wound  
dressing, wipe or towel. The invention liquid  
management film can be used for general purpose liquid  
30 removal, or drainage, or liquid delivery without a  
directly associated absorbent core. The liquid could  
be delivered to an absorbent body or a surface to which  
the liquid is delivered such as a substrate to be  
coated.

35 The invention liquid management film is formed by  
a replication process using a tool with a negative of  
the liquid management film microstructured grooves.  
The film is formed of a thermoplastic material by  
coating or thermal embossing using the reverse image  
40 tool.

5           In simple embodiments, absorbent articles may  
consist essentially of an absorbent core and liquid  
management film of the invention.

          Various modifications and alterations of this  
invention will become apparent to those skilled in the  
10 art without departing from the scope and spirit of this  
invention.

5

EXAMPLESExample 1 and Comparative Example 1

A liquid management film was prepared that had three small rectangular shaped grooves in the base of larger rectangular shaped main grooves. For comparison a liquid management film having rectangular shaped grooves was prepared that did not have secondary grooves in the base of the grooves.

Each liquid management film was prepared by pressing a 15 mil (0.38 mm) thick sheet of low density polyethylene (LDPE) film with a microstructured nickel tool having on its surface a pattern which was the negative impression of the desired pattern and groove geometry. The nickel tools were produced by shaping a smooth acrylic surface with diamond scoring tools to produce the desired microstructure pattern and then electroplating the structure to form a nickel tool suitable for microreplication. A cross-sectional view of Example 1 is illustrated generally in Fig. 14, except that there are three secondary grooves. The specifications of the tools used to form the Example 1 and comparative Example 1 liquid management films are given in Table I as Patterns 1 and 2, respectively, and are numerically indicated in Fig. 14. The LDPE used to press the samples was TENITE™ 1550P available from Eastman Chemical Co., which has a density of 0.918 gms/cm<sup>3</sup> (ASTM D1505) and a melt flow index of 3.5 gms/10 minutes (ASTM D1238, condition 190/2.16). 0.3 weight percent of TRITON™ X-100 surfactant (available from Union Carbide) had been blended with the polyethylene resin as an additive at the time that the film was extruded. The LDPE films were pressed with

5 the microstructured nickel tool in a platen press for  
30 seconds at 149°C and 250 PSI, and then were  
immediately water cooled. Then resulting liquid  
management films were substantially exact replication  
of the microstructured tool such that the groove depth,  
10 width and overall shape did not significantly vary  
along the length of the film.

The liquid management films were tested for  
vertical wicking in accordance with DIN 53924  
("Deutsches Institut Fuer Normung"). The vertical  
15 height achieved in three minutes by a test fluid was  
measured. The test fluid used was deionized water  
containing 0.1 weight percent of a fluorescent dye, 2-  
(6-hydroxy-3-oxo-3H-xanthen-9-yl) benzoic acid disodium  
salt, a fluorescent disodium salt from Eastman Kodak  
20 Company. This liquid has been determined, using the  
Wilhelmy Balance Technique, to have a surface tension  
of about 74 to 75 dynes/centimeter.

The following vertical wicking results were  
obtained. The results are given in centimeters and  
25 represent an average of four tests carried out for each  
liquid management film type.

<u>Example</u>	<u>Pattern #</u>	<u>Vertical Wicking</u>
1	1	12.4
C1	2	4.3

The data shows that a liquid management film  
30 having small rectangular shaped secondary grooves in  
the base of larger rectangular shaped primary grooves  
had significantly improved vertical wicking performance  
compared to a liquid management film having rectangular

5 shaped primary grooves that did not have secondary grooves.

Example 2 and Comparative Example 2

10 A liquid management film was prepared that had two small 40 degree V-groove shaped secondary grooves in the base of larger 60 degree V-groove shaped primary grooves. For comparison a liquid management film having 60 degree V-groove shaped primary grooves was prepared that did not have secondary grooves.

15 The liquid management films were prepared according to the method described above. The specifications of the tools used to form the V-groove shaped grooves are given in Table II (as Patterns 3 and 4). The liquid management film is substantially that depicted in Fig. 9 except that there are only two  
20 secondary grooves. As in Example 1 film, the groove depth, width and overall shape did not vary over the length of the film.

The liquid management films were tested for  
25 vertical wicking as described in Example 1. The following vertical wicking results were obtained. The results are given in centimeters and represent an average of four tests carried out for each liquid management film type.

30

<u>Example</u>	<u>Pattern #</u>	<u>Vertical Wicking</u>
2	3	9.6
C2	4	5.7

The data shows that a liquid management film having small V-groove shaped secondary grooves in the base of larger V-groove shaped primary grooves had

- 5 improved vertical wicking performance compared to a liquid management film having V-groove shaped primary grooves that did not have secondary grooves.

10 Table II

	Pattern 3	Pattern 4
Primary groove angular width	60°	60°
Primary groove spacing	796µm	796µm
Primary groove depth	635µm	635µm
Notch included angle	40°	60°
Secondary groove angular width	40°	NA
Secondary groove spacing	63µm	NA
Secondary groove depth	178µm	NA
Primary groove wall angular width	60°	60°

Examples 3 and 4

Tool Patterns 5 and 6 (see Table I) were used to prepare a liquid management film having four small rectangular shaped channels in the base of larger rectangular shaped main channels (Example 3) as shown in Fig. 14, except that with Example 4 the secondary peaks were sharp V shaped peaks rather the flat tapered tapered secondary peaks shown in Fig. 14.

20 The film samples were prepared by cast extrusion of a LDPE resin onto a rotating forming roll using a standard single screw extruder, thus replicating the pattern on the surface of the roll which was the negative impression of the desired groove geometry and pattern. The temperature of the forming roll was maintained at 49°C by standard means of internal cooling with circulating water. The LDPE resin used

5 was TENITE™ 18BOA available from Eastman Chemical Co.,  
having a density of 0.923 gms/cm<sup>3</sup> (ASTM D1505) and a  
melt flow index of 20 gms/10 minutes (ASTM D1238,  
condition 190/2.16). Approximately 0.5 weight percent  
of TRITON™ X-100 surfactant was blended with the LDPE  
10 resin as an additive at the time of extrusion.

To assess the down web fidelity of the secondary  
groove structure for the liquid management films, notch  
radius of curvature measurements were obtained for each  
sample at locations along the length of three separate  
15 primary grooves of each liquid management film. The  
longitudinal spacing between the radius of curvature  
measurements for each groove was 20-25cm.

The notch angle (34) used to measure the radius of  
curvature (43) is shown in Fig. 14, the notch adjacent  
20 the primary groove sidewall. The notch radius of  
curvature measurements of the liquid management films  
were obtained by taking a photomicrograph of the groove  
cross section with a scanning electron microscope. The  
liquid management films were potted in a dental  
25 impression resin which was allowed to cure. Then the  
sample was microtomed with a razor to leave an exposed  
cross section of the groove. A photomicrograph of this  
prepared sample was then taken. Tangent lines were  
drawn along several points of the tip of the groove.  
30 Normal lines to where the tangents contacted the groove  
were drawn and the location of their intersection  
identified as the center of curvature of the groove.  
An average arc radius was then fit to the tip  
curvature, with the center being the intersection of  
35 the normal lines. The arc radius length was then  
recorded as the radius of curvature.

5           The radius of curvature data (in microns) are summarized in Tables III and IV.

Table III

Example 3 (Pattern 5)	Groove 1	Groove 2	Groove 3
measurement 1	3.1	1.0	2.6
measurement 2	1.0	1.2	2.2
measurement 3	2.5	1.7	1.3

10

Table IV

Example 4 (Pattern 6)	Groove 1	Groove 2	Groove 3
measurement 1	2.6	3.2	2.4
measurement 2	3.2	3.2	2.8
measurement 3	3.2	2.2	(not measured)

Notch radius of curvature measurements and  
15 vertical wicking data were obtained for sheet samples of the Example 3 liquid management film before and after thermal treatment at several different temperatures. The sheet samples were heated in an oven for 50 minutes at temperatures of 90°C, 95°C, 100°C,  
20 105°C, and 110°C. After air cooling, two or three notch radius of curvature measurements were obtained for each heat treated sample. Vertical wicking data was also obtained for each heat treated sample. Vertical wicking was measured as described in Example 1  
25 except that the test fluid comprised 0.5 weight percent of sodium chloride and 0.1 weight percent of the fluorescent dye. The results reported are an average

5 of three measurements. The radius of curvature data and vertical wicking data are summarized in Table V.

Table V

Sample	Notch radius of curvature (microns)	Vertical wicking (cm)
Example 3 (control)	1.7, 1.2 (1.5 avg)	8.2
Example 3 after 90°C	4.2, 4.0 (4.1 avg)	5.4
Example 3 after 95°C	4.0, 4.1, 6.3 (4.8 avg)	5.1
Example 3 after 100°C	4.4, 6.9, 6.3 (5.9 avg)	4.4
Example 3 after 105°C	5.8, 6.7 (6.3 avg)	4.5
Example 3 after 110°C	13.0, 6.4 (9.7 avg)	4.3

10 In a separate series of thermal treatments, sheet samples of the Example 3 fluid management film were subjected to temperatures >110°C. Samples were heated in an oven for 50 minutes at temperatures of 111°C,  
 15 112°C, 113°C, 114°C, and 115°C. After air cooling, notch radius of curvature measurements and vertical wicking data were obtained as described above. The data are summarized in Table VI.

Table VI

Sample	Notch radius of curvature (microns)	Vertical wicking (cm)
Example 3 after 111°C	10.9, 10.8, 12.2 (11.3 avg)	6.9
Example 3 after 112°C	13.1, 12.3, 13.1 (12.8 avg)	6.8
Example 3 after 113°C	12.0, 13.8, 13.2 (13.0 avg)	6.6
Example 3 after 114°C	12.0, 9.7, 9.2 (10.3 avg)	3.7
Example 3 after 115°C	78.4, 32.8, 78.9 (63.4 avg)	2.2

25 Notch radius of curvature measurements and vertical wicking data were also obtained for samples of the Example 4 liquid management film before and after thermal treatment at several different temperatures. The samples were heated in an oven for 50 minutes at

5 temperatures of 90°C, 95°C, 100°C, 105°C, and 110°C.  
After air cooling, two or three notch radius of  
curvature measurements were obtained for each heat  
treated sample. The average of these measurements is  
reported. Vertical wicking data was also obtained for  
10 each heat treated sample according to the method  
described for Example 3. The results reported are an  
average of three measurements. The radius of curvature  
data and vertical wicking data are summarized in Table  
VII.

15

Table VII

Sample	Notch radius of curvature (microns)	Vertical wicking (cm)
Example 4 (control)	1.7	7.2
Example 4 after 90°C	2.3	6.3
Example 4 after 95°C	2.8	6.2
Example 4 after 100°C	2.0	6.1
Example 4 after 105°C	4.6	5.5
Example 4 after 110°C	4.7	5.3

20 Thermal treatment of the liquid management films  
resulted in an increase in the radius of curvature  
values (decrease in notch sharpness) and a  
corresponding decrease in the vertical wicking  
capability of the channels. At 115°C the Example 3  
25 film became distorted resulting in significant loss in  
fidelity of the notch radius of curvature as well as  
the primary and secondary groove depth, width and  
overall shape.

5    Comparative Example 3

          In an effort to prepare a liquid management film via a profile extrusion process, TENITE™ 1550P LDPE blended with 0.5% by weight TRITON™ X-100 was extruded through a die that had attached to the die lip the  
10    microstructured nickel tool that was used to prepare Example 2. A single screw extruder was used operating at a screw speed of 40 rpm to produce an output speed for the extruded strip of ~6.5 meters per minute. The extruded strip was immediately quenched in a cold (~  
15    10°C) water bath.

          Samples of the profile extruded strips were tested for vertical wicking as described in Examples 3 and 4.

          The samples did not vertically wick the fluid. It appeared that this process produced blunt notches which  
20    resulted in a dramatic reduction in vertical wicking capability compared to liquid management films that were prepared using a casting process.

5 What is claimed is:

1. A liquid management film for use in rapid  
transport of liquid comprising a thermoplastic film  
having at least one microstructured hydrophilic surface  
10 with a plurality of primary grooves to promote the  
undirectional spreading of liquids, a plurality of said  
primary grooves having at least two secondary grooves,  
each of said secondary grooves forming at least one  
notch which notches are substantially parallel and  
15 separated by a secondary peak which notches or  
secondary grooves have an included angle of from about  
10° to about 120°, the depth of one of said secondary  
grooves (the height of the secondary peak over the  
notch) being at least 5 microns and said depth being  
20 from about 0.5 to about 80 percent of the depth of the  
primary groove said notches having a radius of  
curvature of less than about 15 microns and the primary  
and/or secondary groove depth and width varies by less  
than 20 percent for each groove over a given length of  
25 the film.

2. The liquid management film of claim 1 wherein  
the primary grooves have a depth of from 50 to 3000  
microns and the depth of the secondary grooves is from  
30 5 to 50 percent of the depth of the primary grooves.

3. The liquid management film of claim 1 wherein  
the secondary grooves are V-shaped or rectangular.

35 4. The liquid management film of claim 2 wherein  
the primary grooves are V-shaped having an included  
angle of from about 10° to about 120°.

5           5.    The liquid management film of claim 2 wherein  
the primary grooves are rectangular.

          6.    The liquid management film of claim 2 wherein  
the included angles of said secondary grooves or  
10 notches are between about 10° and 100°.

          7.    The liquid management film of claim 2 wherein  
where the included angles of said secondary grooves or  
notches are between about 20° and 95°.

15           8.    The liquid management film of claim 2 wherein  
where the width and depth of each of said primary  
grooves varies by less than 10 percent over the length  
of said film.

20           9.    The liquid management film of claim 2 wherein  
said primary grooves are between about 50 and about  
3000 microns deep.

25           10.   The liquid management film of claim 2 wherein  
said primary grooves are between about 75 and about  
1500 microns deep.

          11.   The liquid management film of claim 2 wherein  
30 said primary grooves are between about 100 and about  
1000 microns deep.

          12.   The liquid management film of claim 4 wherein  
the angular width of said primary grooves is between  
35 about 30° and about 90°.

          13.   The liquid management film of claim 2 wherein  
said secondary grooves notches included angle is a  
secant angle taken from the notch to points halfway up  
40 the secondary groove sidewalls.

5           14. The liquid management film of claim 2 wherein  
said notches have a radius of curvature of about 10  
microns or less.

10           15. The liquid management film of claim 2 wherein  
said notches have a radius of curvature of about 5  
microns or less.

15           16. The liquid management film of claim 2 wherein  
said secondary grooves have a plurality of outwardly  
flaring walls.

            17. The liquid management film of claim 2 wherein  
said film is impermeable to aqueous liquids.

20           18. The liquid management film of claim 2 wherein  
said liquid management film has an average thickness of  
between about 25 and 1500 microns.

25           19. The liquid management film of claim 18  
wherein said liquid management film has an average  
thickness of between about 125 and 1000 microns.

30           20. The liquid management film of claim 2 wherein  
said liquid management film has one or more apertures  
therein.

35           21. The liquid management film of claim 2 wherein  
said liquid management film is made of one or more  
polyolefins.

            22. The liquid management film of claim 2 wherein  
each of said primary grooves has three or more  
secondary grooves defining three or more notches.

40           23. The liquid management film of claim 2 wherein  
each of said primary grooves has three or more notches.

5

24. The liquid management film of claim 2 wherein said film is flexible.

10 25. The liquid management film of claim 2 wherein the depth of the secondary grooves is 5 to 50 percent of the depth of the primary grooves.

15 26. The liquid management film of claim 4 wherein the primary grooves have an angular width greater than the angular width of the secondary grooves.

20 27. The liquid management film of claim 1 wherein the secondary grooves are substantially rectangular and each has two notches.

25 28. The liquid management film of claim 24 wherein the secondary grooves are substantially rectangular and each has two notches where the bottoms of the rectangular grooves are at least 3 microns wide to form parallel thin film regions.

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 A61F B32B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US 5 514 120 A (JOHNSTON RAYMOND P ET AL) 7 May 1996 see claims; figures ---	1-28
A	WO 96 07384 A (KIMBERLY CLARK CO) 14 March 1996 see claims; figure 6 ---	1, 3, 4, 6, 7, 12
A	EP 0 178 108 A (SMITH & NEPHEW ASS) 16 April 1986 see page 6, line 5 - page 8, line 12; claims 1, 3, 5, 8, 10; figure 1 ---	1, 17, 18, 21
A	EP 0 117 351 A (JOHNSON & JOHNSON) 5 September 1984 see page 3, line 14 - line 20; claims 1-5; figures --- -/-	1

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

° Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance  
"E" earlier document but published on or after the international filing date  
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)  
"O" document referring to an oral disclosure, use, exhibition or other means  
"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention  
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone  
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.  
"&" document member of the same patent family

Date of the actual completion of the international search

28 April 1998

Date of mailing of the international search report

08/05/1998

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040, Tx. 31 651 epo nl,  
Fax: (+31-70) 340-3016

Authorized officer

Mirza, A

# INTERNATIONAL SEARCH REPORT
